Climate
Centre

The IFRC carries out relief operations to assist victims of disasters, and combines this with development work to strengthen the capacities of its member National Societies.

The Climate Centre is a specialist reference centre of the IFRC that helps reduce the impacts of climate change and extreme-weather events on vulnerable people.

Ethiopia is the second most populous country in Africa and has hopes to be the continent's largest energy exporter.

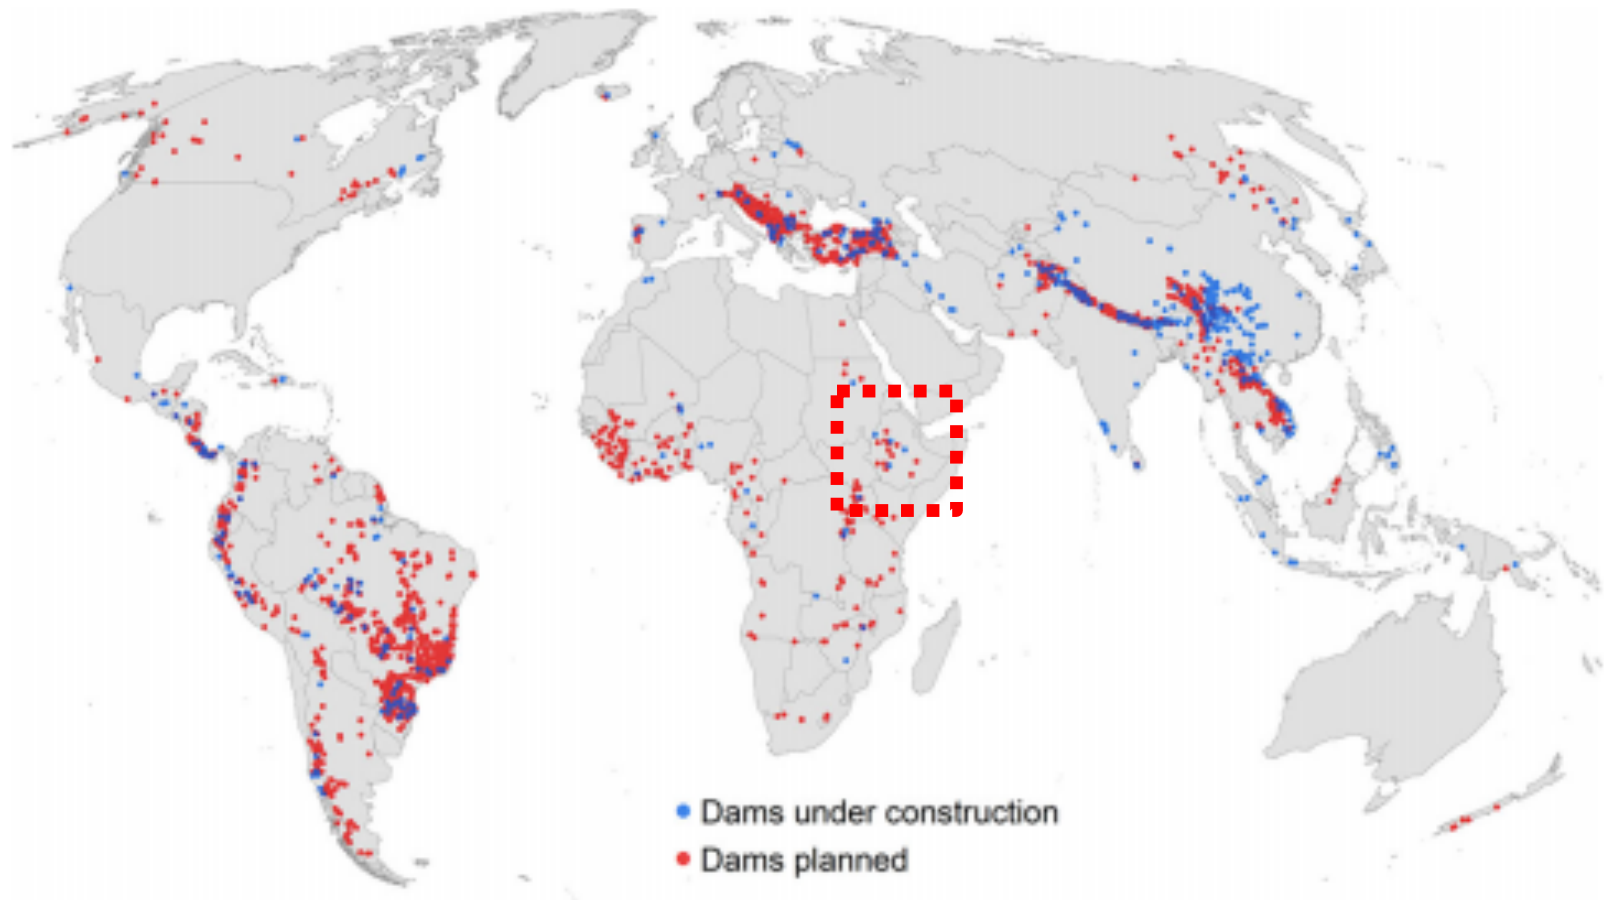

WORLD

Troubled Waters: Egypt and Ethiopia Wrangle Over Nile Dam

Addis Ababa's plans expose rivalry with Cairo for regional power; 'Egypt cannot live without the Nile'

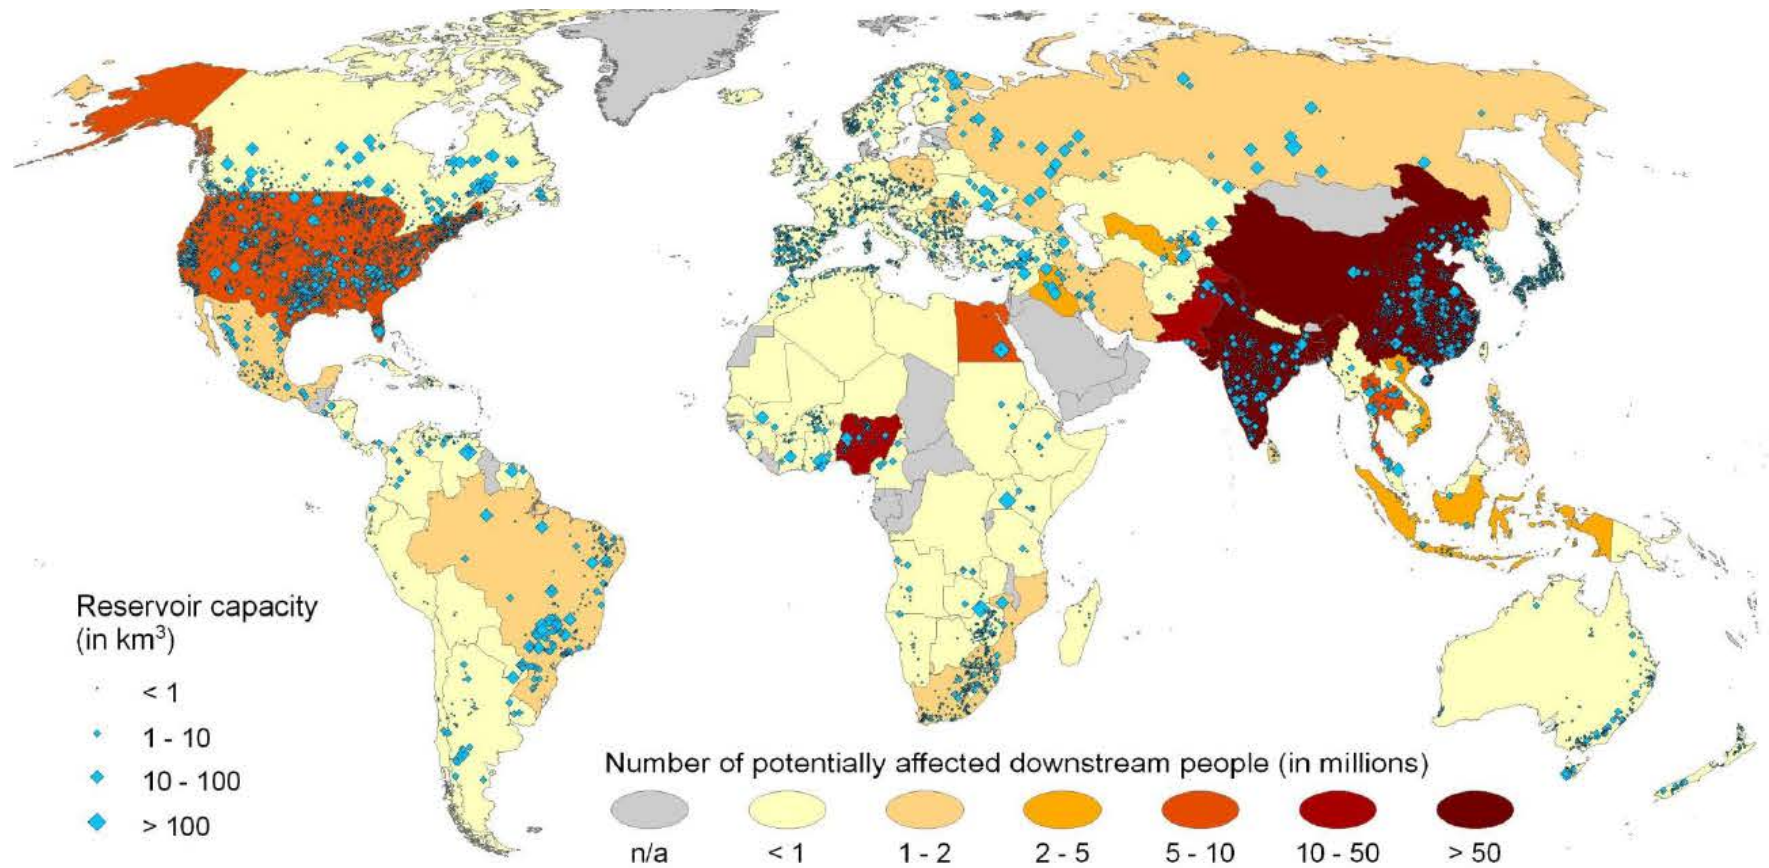

(<https://www.wsj.com/articles/troubled-waters-egypt-and-ethiopia-wrangle-over-nile-dam-1516185001>)

A 2014 study estimated that 3700 new hydroelectric dams (>1 MW) are planned or under construction, increasing global hydropower production by 73%.

(Zarfl et al, 2014)

Populations living downstream of dams may have their livelihoods disrupted by dam-induced alterations of river flows.

(Richter et al, 2014)

Background

Flood Modelling

Community Assessments

Next Steps

The Climate Centre successfully piloted FUNES, a self-learning algorithm which uses minimal data inputs to improve the timing of water releases from hydroelectric dams, in 2016.

(Suarez and de Suarez, 2014)

This study focused on Koka Dam, Ethiopia's oldest hydroelectric dam, with the following objectives:

- 1. Identify forecasts of natural phenomena (e.g., precipitation, hydrology) that anticipate extreme events.**
- 2. Assess what is known and what needs to be known to link forecasts with anticipated impacts.**
- 3. Suggest actions worth taking once the forecast exceeds a predefined threshold of risk before the impacts materialize.**
- 4. Outline proposed next steps for a forecast-based contingency plan.**

Research Overview: Objectives and Project Scope

Flood Modelling: Background and Findings

Community Assessments: Findings and Recommendations

Conclusion: Next Steps

- 1. Identify forecasts of natural phenomena (e.g., precipitation, hydrology) that anticipate extreme events.**
- 2. Assess what is known and what needs to be known to link forecasts with anticipated impacts.**
3. Suggest actions worth taking once the forecast exceeds a predefined threshold of risk before the impacts materialize.
4. Outline proposed next steps for a forecast-based contingency plan.

HEC-GeoRAS is a river analysis system that allows users to view results in a geospatial context.

Geographic data
developed in
ArcGIS

Geographic data
imported into HEC-
RAS for hydraulic
modelling

HEC-RAS results
exported to ArcGIS
for geospatial
context

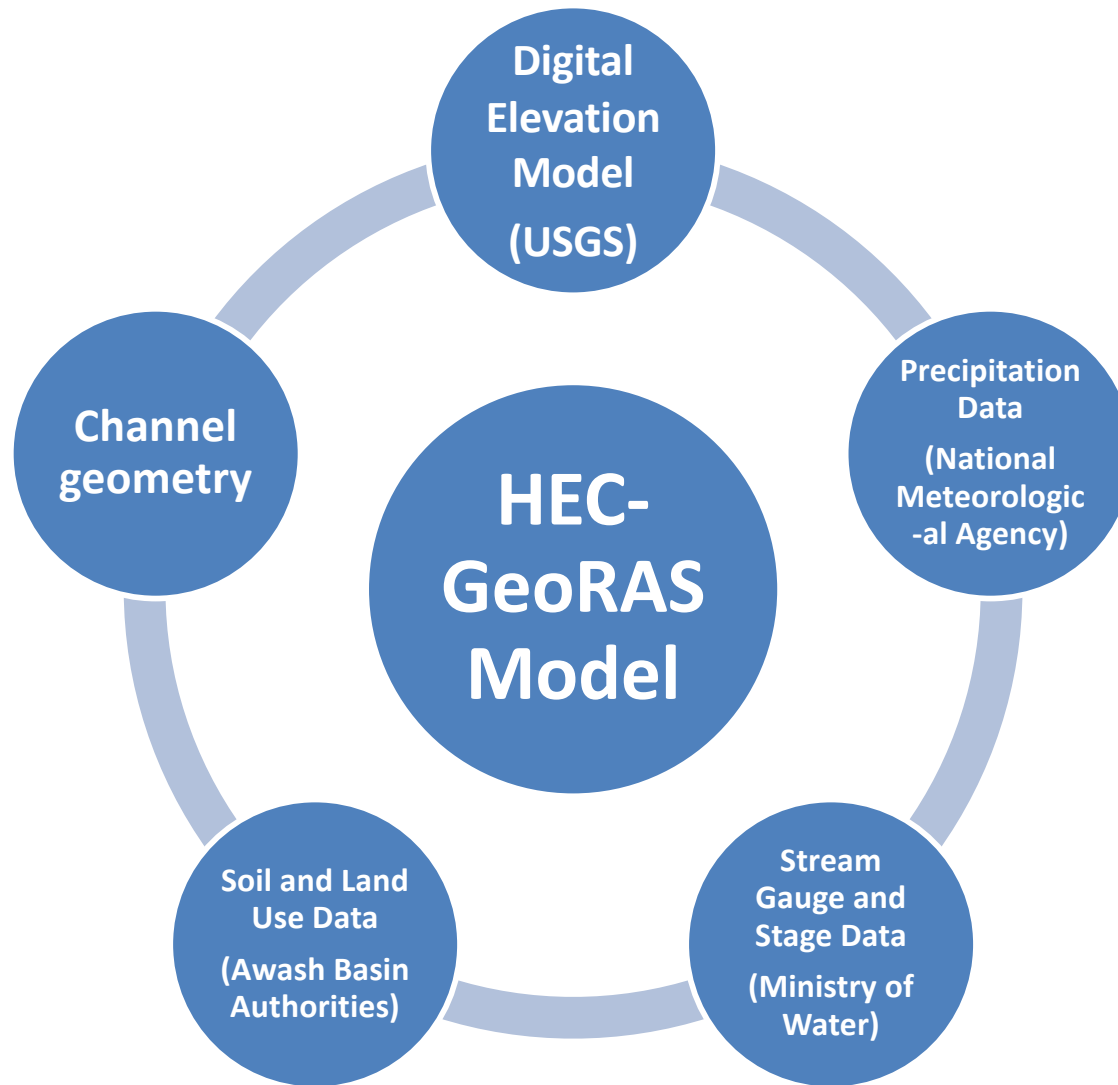

Background

Flood Modelling

Community Assessments

Next Steps

The modelling software requires a number of inputs to produce an accurate and reliable model.

Flood modelling, using HEC-GeoRAS, was performed for downstream communities of Koka Dam.

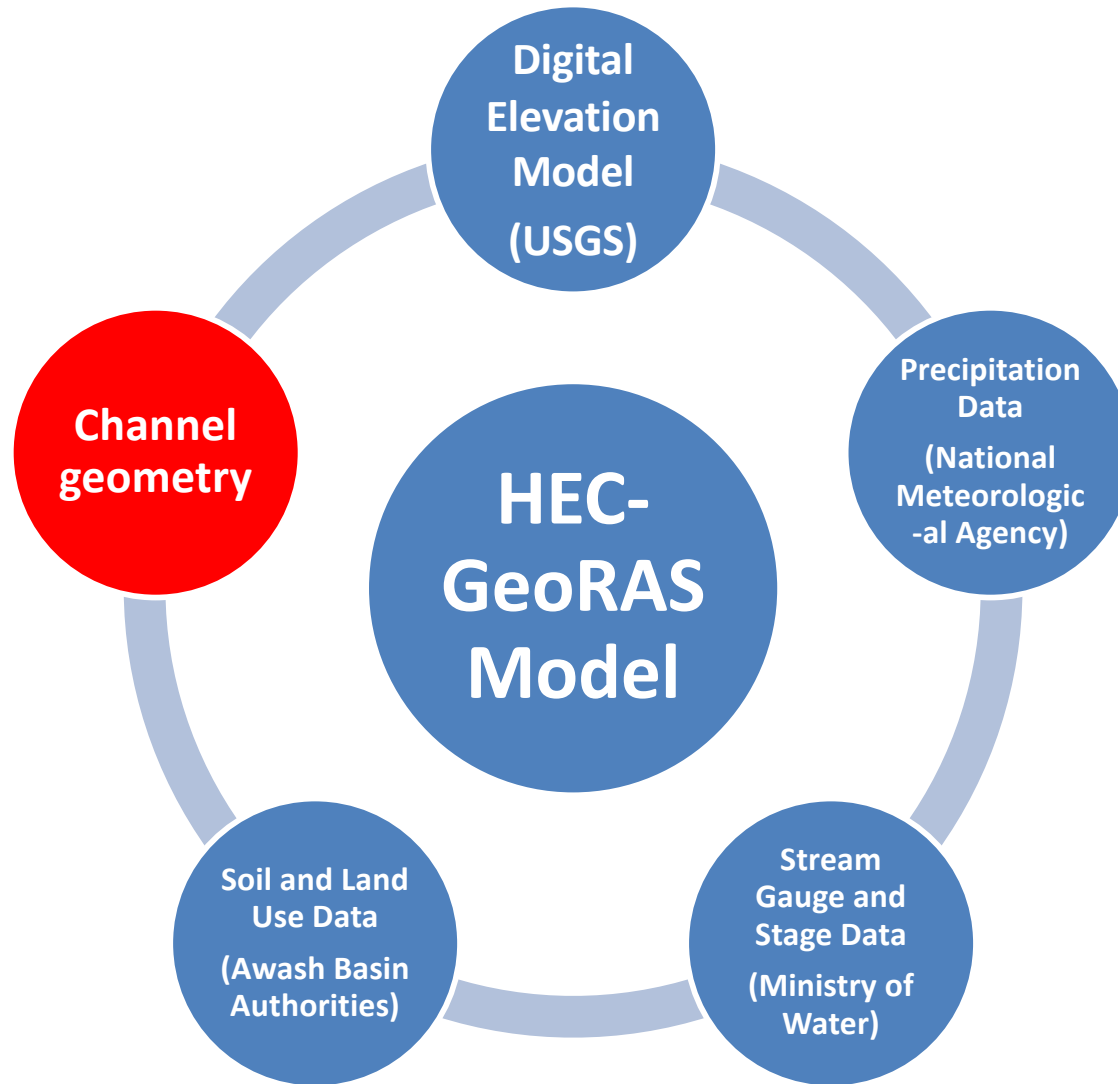

A combination of precipitation and controlled releases likely result in downstream flooding.

Flooding primarily affects agricultural areas along Awash River.

The lack of available data presented challenges towards determining the *amount* of water that can be safely released from the dam.

The lack of available data presented challenges towards determining the *amount* of water that can be safely released from the dam.

Channel
geometry

The lack of available data presented challenges towards determining the *amount* of water that can be safely released from the dam.

The lack of available data presented challenges towards determining the *amount* of water that can be safely released from the dam.

What's needed?

1. Recent stream gauge and stage data (most recent is from 2007).
2. Documentation of flooding dates in downstream communities to concretely link these events with natural phenomena.
3. Updated and ample channel geometry to estimate *how much* water can be released from Koka Dam without negative downstream consequences.
4. Maps of officially and unofficially constructed dikes.

- 1. Identify forecasts of natural phenomena (e.g., precipitation, hydrology) that anticipate extreme events.**
- 2. Assess what is known and what needs to be known to link forecasts with anticipated impacts.**
3. Suggest actions worth taking once the forecast exceeds a predefined threshold of risk before the impacts materialize.
4. Outline proposed next steps for a forecast-based contingency plan.

Research Overview: Objectives and Project Scope

Community Assessments: Findings and Recommendations

Conclusion: Next Steps

1. Identify forecasts of natural phenomena (e.g., precipitation, hydrology) that anticipate extreme events.
2. Assess what is known and what needs to be known to link forecasts with anticipated impacts.
3. **Suggest actions worth taking once the forecast exceeds a predefined threshold of risk before the impacts materialize.**
4. Outline proposed next steps for a forecast-based contingency plan.

Assessments were performed in seven communities and two facilities downstream of Koka Dam.

Assessments were performed in seven communities and two facilities.

Communities	Facilities
Kuriftu	Sodere Resort
Melka Adama	Wonji Sugar Factory
Botu Kurabu	
Bati Germana	
Qechachule Guja	
Koloba Bli	
Bato Degaga	

All informants reported flooding in their community or facility.

Flooding primarily impacts agricultural land, and the primary occupation of downstream communities is agriculture.

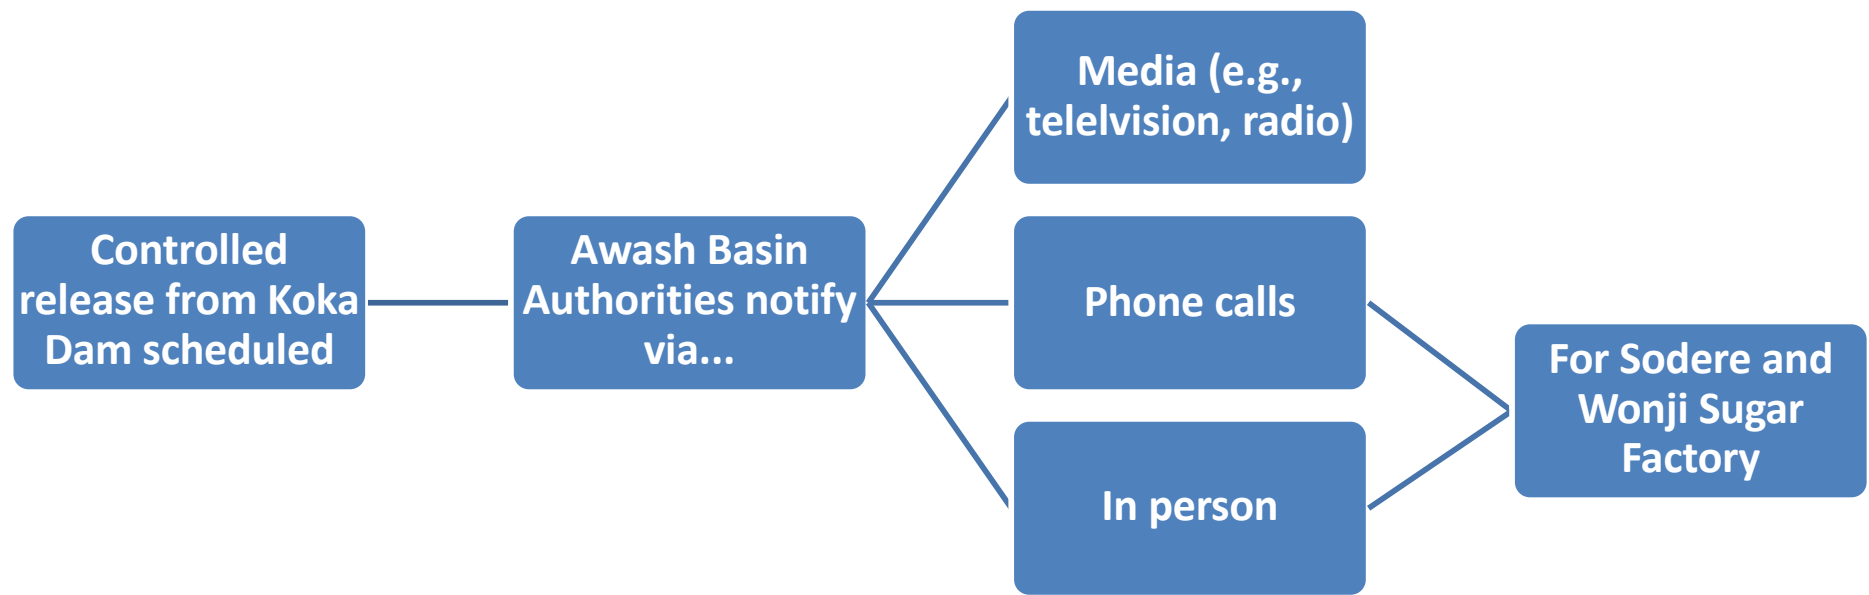

Over half of the informants also reported increased cases of malaria following flooding.

(Maes et al, 2014)

Minimizing flood impacts can allow communities to generate additional income, improve health, and improve their livelihoods.

The existing warning system is between the Awash Basin Authorities and downstream communities/facilities.

The two facilities were satisfied with the current *method* of notification. Communities has several recommendations:

In-person notification

Mobile phone notification:

- **Phone calls to central members of community, who will further disseminate information**
- **SMS text message notification**

Notifying local agricultural officers

All informants expressed desire for a change in the *timing* and *content* of the warnings, including:

Earlier notification, if possible.

- **Current early actions include moving livestock and irrigation pumps from the floodplain. More time would allow for additional preparation.**

Anticipated impacts associated with the floods.

1. Identify forecasts of natural phenomena (e.g., precipitation, hydrology) that anticipate extreme events.
2. Assess what is known and what needs to be known to link forecasts with anticipated impacts.
3. **Suggest actions worth taking once the forecast exceeds a predefined threshold of risk before the impacts materialize.**
4. Outline proposed next steps for a forecast-based contingency plan.

2. Assess what is known and what needs to be known to link forecasts with anticipated impacts.
3. Suggest actions worth taking once the forecast exceeds a predefined threshold of risk before the impacts materialize.
4. **Outline proposed next steps for a forecast-based contingency plan.**

FUNES can be piloted on Koka Dam.

Infrastructure investments can provide long-term resilience.

Dikes can be built along the river to prevent flooding from the river.

Channels and canals can be built through farmland to direct flow from communities to river.

Minimizing flood impacts can allow communities to generate additional income, improve health, and improve their livelihoods.
